With bone scanning this leads to high sensitivity for focal disease if there has been any disturbance of skeletal metabolism. However. in many other clinical situations. and particularly in metabolic bone disease. more generalised alteration in skeletal turnover may occur. and quantitation of diphosphonate uptake by the skeleton can provide valuable clinical information.

Thus, in clinical practice, a treatment-induced BMD increase can only be detected in general after 2 years. 35 However, in patients receiving long-term steroid therapy, the changes in BMD may be so important that they can be detected after 1 year. Thus, although the spine may not be the best site for the diagnosis of osteoporosis given the high prevalence of spinal degenerative disease, it may be the most sensitive site for detecting changes over time.

A bone scan is also called a radionucleotide scan, scintigram or nuclear medicine test. A large camera (called a gamma camera) scans you and picks up radioactivity. You have the scan in either the medical physics, nuclear medicine or x-ray department at the hospital. The scan can take between 30 to 60 minutes, but you'll be at the hospital for several hours. Many prostate cancers stay within the prostate for years.
